PROVISIONAL SPECIFICATION

FOR THE INVENTION ENTITLED:-

"SYSTEM FOR HIP REVISION SURGERY"

The invention is described in the following statement:-

FIELD OF THE INVENTION

The present invention relates to methods for surgery and in particular to a method for removing unwanted material from within a bone. It has been developed primarily for removing bonding material from within a femur during hip revision surgery and will be described hereinafter with reference to this application. However, it will be appreciated that the invention is not limited to this particular field of use.

BACKGROUND OF THE INVENTION

Prior art hip replacement surgical techniques typically involve a surgeon firstly making a fairly large initial incision so as to reveal the hip joint. The surgeon then typically manipulates the leg of the patient to dislocate the hip bone. This often requires the application of significant force to effect dislocation. Excessive manipulation and application of force may cause collateral damage to the patient, possibly resulting in post operative pain and/or an extended healing time. The head of the femur is then cut off at the neck. A cavity is reamed into the hip to accept a prosthetic acetabular cup (for example a LINK T.O.P. Acetabular Cup) and a prosthetic stem (for example a LINK C.F.P. Hip Stem) is inserted into the femoral shaft. A bonding agent, such as surgical cement, is typically used to bond the prosthetic acetabular cup into the cavity in the hip and to bond the prosthetic stem to the femoral shaft. Typically, the surgeon aligns the cutting and reaming tools by eye, possibly resulting in minor misalignments. Hence, once the prosthetics are installed, there may be visually imperceptible misalignments between the prosthetic acetabular cup and the prosthetic femoral head. This may result in problems such as misalignment of the leg, incorrect leg length and/or incorrect soft tissue tension. Additionally, in the long term, misaligned prosthetic components may wear more quickly, giving rise to aseptic loosening of components and potentially necessitating early repetition of the surgery.

Due to prosthetic component wear over time giving rise to aseptic loosening of components, many patients require repetition of the surgery. This repetition of surgery or hip revision surgery involves replacement of the prosthetic components. It is therefore necessary to remove the worn out components so that they can be replaced with new prosthetics. The removal techniques typically involve a surgeon removing or chipping the old cement away from within the femur and hip of the patient, so that the new prosthetics can be installed. While the surgeon is removing the old cement, there is a risk that the chipping will cause the bone to collapse and break. This can result in complications to the surgery.

Any discussion of the prior art throughout the specification should in no way be considered as an admission that such prior art is widely known or forms part of the common general knowledge in the field.

DISCLOSURE OF THE INVENTION

It is an object of the present invention to overcome or ameliorate at least one of the disadvantages of the prior art, or to provide a useful alternative.

It is an object of the present invention in its preferred form to provide a method for more safely removing unwanted material from within the femur of a patient during hip revision surgery.

According to one aspect of the invention there is provided a method of removing unwanted material from within a cavity of a bone during surgery, said method including the steps of:

- a) exposing said bone;
- b) applying at least one support means to said bone to support the structure of said bone; and
- c) removing said material from within said bone cavity.

According to a second aspect the present invention provides a support arrangement for use in supporting a bone during a surgical operation, the arrangement including one or more supports located by a guide means, each support including means to fit around and support said bone during said operation.

5 Preferably, said support means or support includes a surgical tool guide means to guide a cutting tool for removing said material.

For preference, the support means or support is a surgical clamp including two arms hingedly connected at substantially their proximal ends, each of said arms respectively including one of a pair of opposable gripping formations at its distal end. Preferably, the
10 surgical clamp includes an adjustment means for selectively moving said arms into and out of gripping engagement with the bone. Preferably, the adjustment means is located at or adjacent said proximal ends of the arms. The adjustment means may include a shaft threadedly engaged through one said arm; a handle located at one end of said shaft; and an abutment portion located at the other end of said shaft such that relative rotation
15 of said handle brings said abutment portion into and out of abutment with the other said arm thereby moving said gripping formations into and out of gripping engagement. The gripping formations are preferably concave to fit snugly around the outer surface of the bone.

Preferably, a plurality of support means are positioned along the bone to fully
20 support it along its length. Desirably, each support means is aligned relative to the longitudinal axis of the bone cavity.

For preference, the surgical tool guide means includes a guide rail mounted to at least one of said arms wherein said guide rail is adapted to receive a guide display for displaying the orientation of said bone. Preferably, the guide display is a guide rod
25 slidably mounted to the guide rail.

According to a third aspect the present invention provides a surgical chisel for use in the method of the first aspect, said chisel including:

- a shaft having a hollow portion adjacent a cutting end;
- an abutment portion at the other end of said shaft;
- 5 the hollow portion having tapering internal walls extending inwardly towards a central axis of the shaft to define a cutting edge at said cutting end.

Preferably, the hollow portion extends along a major portion of the length of said shaft. For preference, said shaft is generally circular in cross section.

In another aspect, the present invention provides a method of performing hip
10 revision surgery on a patient, said method including the steps of:

- a) exposing a femoral bone formation of said patient;
- b) applying at least one support means to said femoral bone formation to support the structure of femoral formation; and
- c) removing unwanted material from within said femoral bone formation.

15

BRIEF DESCRIPTION OF THE DRAWINGS

A preferred embodiment of the invention will now be described, by way of example only, with reference to the accompanying drawings in which:

Figure 1 is a front view of a surgical clamp according to the preferred embodiment of
20 the invention shown supporting a femoral bone formation;

Figure 2 is a side view of the surgical clamp shown in Figure 1;

Figure 3 is an enlarged front view of an adjusting formation according to a preferred embodiment of the present invention;

Figure 4 is a side view of the adjusting formation shown in Figure 3;

Figure 5 is an enlarged cut-away view of a guide rail according to a preferred embodiment of the present invention;

Figure 6 is a front view of a surgical cutting tool according to a preferred embodiment of the present invention; and

5 Figure 7 is a depiction of a femoral shaft illustrating a preferred embodiment of the invention shown supporting the structure of the femoral shaft.

PREFERRED EMBODIMENT OF THE INVENTION

Referring to the drawings, the support means in the form of a surgical clamp 1 includes two arms 2 and 3. The arms are hingedly connected at substantially their
10 proximal ends 4 and 5. Each of the arms respectively includes one of a pair of opposable gripping formations 6 and 7 at its distal end 8. In this embodiment, the gripping formations are concave. The surgical clamp 1 includes an adjusting formation 9 for selectively moving the arms 2 and 3 into and out of gripping engagement with the outer surface 10 of a femoral bone formation 11. The adjusting formation includes a
15 shaft 12 threadedly engaged through one of the arms 3. A handle 13 is located at one end 14 of the shaft 12 and an abutment portion 15 is located at the other end 16 of the shaft. Relative rotation of the handle 13 selectively brings the abutment portion 15 into and out of abutment with the other arm 2, thereby moving the gripping formations 6 and 7 into and out of gripping engagement. A surgical tool guide means, in the form of a
20 guide rail 17, is mounted to arm 3 to guide a cutting tool for removing unwanted material such as glue or cement from within the femoral bone formation 11. The guide rail 17 is adapted to receive a guide display, in the form of a guide rod 19, which is slidably mounted to the guide rail 17 for displaying the orientation of femoral bone formation 11.

Referring to Figure 6 there is shown a cutting tool in the form of surgical chisel 20. The chisel 20 includes a hollow shaft 21 and an abutment portion 22 at one end 23 of the shaft. A cutting end 24 is provided at the other end of the shaft 21. The cutting end has inwardly tapering walls 25 and 26 which define a cutting edge 27.

- 5 Referring to Figure 7, in use, a number of the clamps 1 are inserted by the surgeon through incisions adjacent the bone and positioned with gripping formations 6 and 7 around the bone formation 11. The arms 2 and 3 are then adjusted by the handle 13 to bring the formations 6 and 7 into supporting engagement of the bone formation 11. Each clamp is aligned respective to each other and the bone formation by guide rail 17.
- 10 As each clamp is of the same length, the guide rail 17 extends generally parallel to and provides a guide as to the longitudinal axis of the bone formation. The rod 19 attached to the rail can thus be used to guide a surgical tool used for cleaning out the cavity of the bone formation.

- Once the bone is fully supported by the clamps, the surgeon can commence
- 15 chiselling removal of cement or other unwanted material from the cavity of the bone formation 11 using chisel 20. The configuration of the chisel 20 allows waste material to be captured and withdrawn by means of the hollow portion. The chisel is typically dimensioned so as to fit neatly within the bone cavity and allow alignment with the guide rod 19. It will be apparent to those in the art that a variety of other means can be
- 20 used to remove unwanted material from the bone cavity provided the bone is adequately supported during removal.
